5.2.1	Spark . . . . .	13
5.2.2	Dask . . . . .	13

# 1 Intro

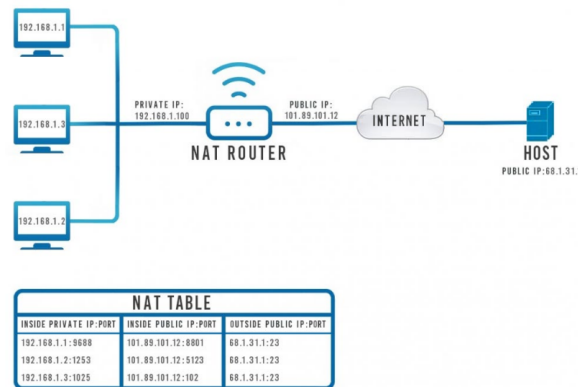

Topics:

- Linux basics + containers
- Elastic search (text search, document store)
- Linux Batch Processing & Dask
- InfluxDB (timeseries)
- Cloud services (Kafka, Kinesis, Lambda, ML services, ...)

## 2 NAT-ing

### 2.1 NAT

= Network Address Translation

Figuur 1: NAT diagram

#### 2.1.1 The problem

- We only have one (public/private) IP-address
  - Howest: 172.23.82.60
- Connecting to a server over a network:
  - Using a protocol (HTTP) which uses TCP
  - Our server has an IP address: 172.23.82.60
  - Our server is listening at port 5000
  - $\Rightarrow$  `http://172.23.82.60:5000`
- Problem: We want to have multiple IP addresses
  - Student 1 wants to reach `http://192.168.20.21:5000`
  - Student 2 wants to reach `http://192.168.20.22:5000`
  - Student x wants to reach `http://192.168.20.xx:5000`

### 2.1.2 The solution

Translation is needed!

- 172.23.82.60:5000 should point to 192.168.20.21:5000
- 172.23.82.60:5001 should point to 192.168.20.22:5000
- 172.23.82.60:5xxx should point to 192.168.20.xx:5000

We can use any port, on both sides:

- 172.23.82.60:8000 can point to 192.168.20.21:5000
- 172.23.82.60:8000 can point to 192.168.20.21:3000

## 2.2 SSH Tunnel

= SSH Port Forwarding

Resource	Internal IP	Username	Password	External port	Internal port
Vyos Router	192.168.50.1	vynos	P@ssw0rd	7000	22
Storage	192.168.50.2	student	P@ssword	n.v.t.	22
SSH	192.168.50.3	student	P@ssword	7040	22
RDP	192.168.50.4	Administrator	P@ssword	7020	3389
vCenter vSphere	192.168.50.10	administrator@vsphere.local	P@ssword	7060	443
vCenter appliance	192.168.50.10	root	P@ssword	n.v.t.	5480
ESXi-00	192.168.50.11	root	P@ssword	n.v.t.	22
ESXi-01	192.168.50.12	root	P@ssword	n.v.t.	22

Figuur 2: Example

Figuur 3: Voorbeeld: een tunnel wordt opengemaakt en er wordt ingelogd in user@instance

## 3 Container technology

### 3.1 Docker

- Docker = ecosystem for creating and running containers
- Docker wants to make it possible to install and run software on any system

- Other reasons: Microservices/DevOps/Resource usage
- Docker != Container
  - Docker CLI
  - Docker Engine
  - Docker Image
  - Docker Container
  - Docker Hub
  - Docker Compose
  - Docker Swarm
  - ...

## 3.2 Microservices

- = A software development technique
- Structure an application as a collection of loosely coupled services
- Lightweight
- Microservices-based architectures enable continuous delivery and deployment
- <https://en.wikipedia.org/wiki/Microservices>

### 3.2.1 Monolithic vs Microservices

Figure 4: Monolithic architecture vs Microservices architecture

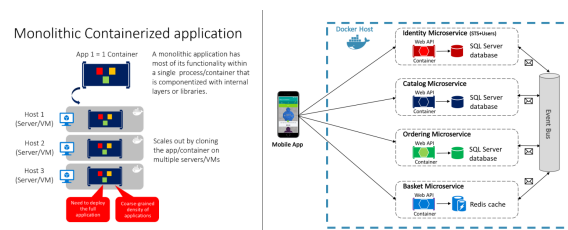

Figure 5: Monolithic Containerized application

Microservices does **not** necessarily mean containerization!

### 3.3 Virtualization vs Containerization

Figuur 6: Virtualization vs Containerization

#### 3.3.1 Virtualization

- = An abstraction of physical hardware turning one server into many servers
- Multiple VMs can run on the same machine
- Each VM includes a full copy of an Operating System (OS), one or more apps
- Takes a lot of space
- Can be slow to boot

#### 3.3.2 Containerization

- = An abstraction at the app layer that packages code and dependencies together
- Multiple containers can run on the same machine, they share the OS kernel with each other, each running as isolated processes in user space.
- Takes up less space than VMs
- Boot up almost instantly

Figuur 7: Schematic

### 3.4 Shared kernel

#### 3.4.1 What is a kernel?

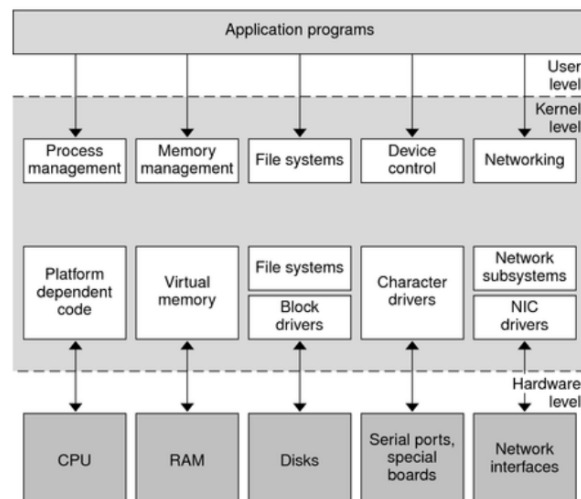

- Piece of software that offers basic functionality to the OS

- System calls: open, read, write, close, wait, exit, . . .
- A typical kernel has a few hundred system calls

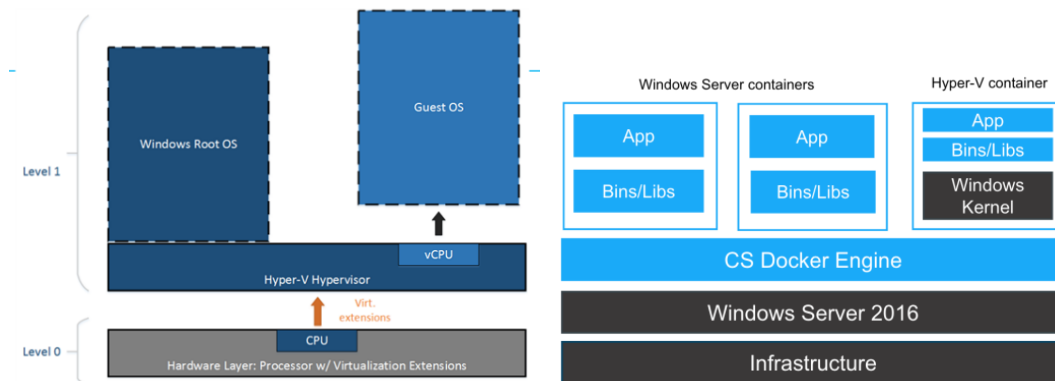

Figuur 8: The kernel is the layer that communicates between hardware and applications

- Docker shares the host OS kernel
  - Host OS: Windows / MacOS / Linux
  - Shared Linux Kernel

Figuur 9: Kernel in detail

- The Ubuntu container requires the Linux kernel
- The Linux kernel runs in a Virtual Machine

Figuur 10

### 3.4.2 How?

Two important Linux kernel features:

- **Namespaces** are a feature of the Linux kernel that partitions kernel resources
- **cgroups** (control groups) is a Linux kernel feature that limits, accounts for, and isolates resource usage of a collection of processes

Simpler:

- Namespaces = isolating resources per process (or group of processes)
- cgroups = Limiting resource usage per process (or group of processes)

### 3.4.3 Namespaces

- 7 types:
  - mount, UTS, IPC, network, PID, cgroup, user
- For the process (or group of processes) it looks like there is a completely isolated set of resources

### 3.4.4 Containers

What is a container?

- One or more running processes (if not running anymore  $\Rightarrow$  container dead)
- Resources are specifically assigned to it
- The real building blocks: Linux kernel features
  - Namespaces
  - cgroups

## 3.5 Images

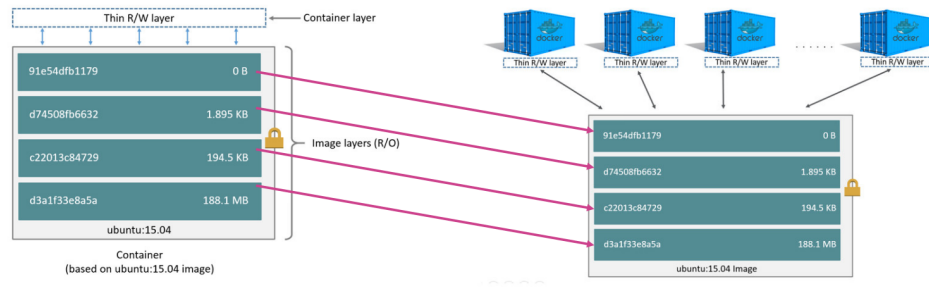

What is an image?

- Filesystem snapshot
- Startup command
- Layered structure (!)

Instance of image = container

### 3.5.1 Image layer

Figuur 11: Image layers

- RUN, COPY, ADD
  - = new read-only layer
- Top layer = container layer
  - Writeable
- Delete container = delete container layer
  - Image will still exist
  - Persistent volumes

### 3.6 Docker is lightweight

- Shared kernel
- Container has no OS
- Less disk space ⇒ sharing layers
- Small community images
  - ex: Alpine Linux (small, simple, secure)
- Current Docker version is using runC (previously LXC = Linux Containers)
  - runC = tooling (written in Go) that makes it possible to create and run containers
  - runC = CLI to 'easily' access kernel features such as cgroups and namespacing
  - runC = successor of libcontainer (developed by Docker)
  - Open-sourced ⇒ better community
  - runC implements 'Open Container Initiative Runtime Specification'

– <https://github.com/opencontainers/runtime-spec>

Docker is ‘nothing more’ than an ecosystem about creating & running containers

## 3.7 Using Docker

(see slides 40-55 in [02\\_big\\_data\\_01\\_containers.pdf](#) for basic commands)

### 3.7.1 Layers bekijken

With the command ‘docker history <image | container id>’ you’ll get an overview of the layers of an image.

- Every RUN, COPY, ADD adds a new read-only layer
- Make Dockerfile more efficient ⇒ create less layers

### 3.7.2 Make Dockerfile more efficient

Our Dockerfile, before optimisation:

```
1 FROM python:3.9.1-alpine3.13
2 WORKDIR '/app'
3 RUN apk add --no-cache linux-headers g++
4 RUN pip install Flask # we can replace these two lines by:
5 RUN pip install uwsgi # RUN pip install -r requirements.txt
6 COPY ./ ./
7 RUN addgroup -S uwsgi && adduser -S uwsgi -G uwsgi
8 USER uwsgi
9 CMD ["uwsgi", "--ini", "app.ini"]
```

After optimisation:

```
1 FROM python:3.9.1-alpine3.13
2 WORKDIR '/app'
3 RUN apk add --no-cache linux-headers g++
4 # the addgroup and adduser commands can be higher up
5 RUN addgroup -S uwsgi && adduser -S uwsgi -G uwsgi
6 # first, we copy the requirements.txt file
7 COPY ./requirements.txt ./
8 # then we install ALL packages
9 RUN pip install -r requirements.txt
10 # then we copy the remaining files
11 COPY ./ ./
12 USER uwsgi
13 CMD ["uwsgi", "--ini", "app.ini"]
```

### 3.7.3 Connecting to a database in a different container

Use ‘ip a’ to find the correct ip to use in this command:

```
1 docker run -p 8080:8080
2 -e POSTGRES_PASSWORD=student_password
```

```

3 -e POSTGRES_USER=student_user
4 -e POSTGRES_DATABASE=labo
5 -e POSTGRES_PORT=5432
6 -e POSTGRES_HOST=ip-van-je-vm # change this ip
7 -e PORT=8080
8 jouw-naam/api # change this

```

## 4 Sharding

- Index = collection of documents
- Document = data in JSON format
- Shard = A piece of an index. Index is "sharded" in blocks, a block = shard
- Primary shard = Document is primarily indexed (written) to a primary shard
- Replica shard = an asynchronous copy of the primary shard

### 4.1 Create index

```

1 {
2   "settings": {
3     "number_of_shards": 2,
4     "number_of_replicas": 1
5   }
6 }

```

How many shards in total: **4**

Figuur 12: 4 shards: 2 primary shards with 1 replica each

### 4.2 Health

Health exists at shard, index and cluster level!

#### 4.2.1 Shard health

- Green = all shards are allocated
- Yellow = all primaries are allocated but at least one replica is not
- Red = at least one primary shard is not allocated in the cluster

#### 4.2.2 Index health

= status of the worst shard in that index

#### 4.2.3 Cluster health

= status of the worst index in the cluster

### 4.3 Shard allocation

Shards states:

- Unassigned = master did not assign the shard (yet)
  - Or master is not able to assign the shard
- Initializing = master did assign the shard, creating...
- Started = shard is fully operational
- Relocating = shard is moving
  - Imbalance, new nodes, removed nodes, ...

#### 4.3.1 Unassigned

Figuur 13: No shards assigned yet

#### 4.3.2 Initializing

Figuur 14: Creating shards

### 4.3.3 Started

Figuur 15: The primary shards have been started, replica 1 is initializing. **Cluster status = yellow**

Figuur 16: **Cluster status = green**

What if one of the node fails?

Figuur 17: Situation when one node fails

Figuur 18: After some time, R2 will become a primary shard. **Cluster status = yellow**

#### 4.3.4 Relocating

Figuur 19: After es02 is restored, P2 gets relocated to its previous node

#### 4.4 Change number of replicas

```
1 {  
2   "index": {  
3     "number_of_replicas": 0  
4   }  
5 }
```

How many shards in total? **2**

Figuur 20: 2 shards total: 2 primary shards, 0 replicas each

##### 4.4.1 Health when one fails

Figuur 21: **Cluster status = Red**

#### 4.5 Caveat: single node cluster

TODO: meer info

- Bootstrap checks = important settings are checked
- discovery.type=single-node
- If a node is already part of a cluster:
  - Unique node ID
  - Unique cluster ID
  - Not easy to create a new cluster

## 5 Linux batching + Dask

### 5.1 Python & data engineering/science

- Veel tools, libraries (numpy, pandas)
- Jammer genoeg slecht schaalbaar  $\Rightarrow$  parallelisatie
- Threads/processes kan, maar complex en niet ideaal
- Wat als het niet in memory past?
  - Naar disk?
  - Kan, maar complex! Sommige operaties 'vereisen' alles in memory

### 5.2 Spark vs Dask

#### 5.2.1 Spark

- Complex, leercurve!
- Complete 'engine', clustering
- Streaming engine
- In Java geschreven: gebruikt de Java Virtual Machine (JVM)  $\Rightarrow$  minder toegankelijk
- Standalone

#### 5.2.2 Dask

- Eenvoudiger (zeker als je Python kent)
- Lightweight, zelfs op 1 node zinnig
- Flexibeler, maar minder performant
- Integratie met andere libraries
- In zekere zin 'de Python versie van Spark'
